### Abstract

In this paper, we introduce the edge-to-edge  $e - e'$  path, the edge-to-edge detour distance  $D(e, e')$ , the edge-to-edge  $e - v$  detour, the edge-to-edge detour eccentricity  $e_{D_3}(e)$ , the edge-to-edge detour radius  $R_3$ , and the edge-to-edge detour diameter  $D_3$  of a connected graph  $G$ , where  $e, e'$  are edges in  $G$ . We determine these parameters for some standard graphs. It is shown that  $R_3 \leq D_3 \leq 2R_3 + 1$  for every connected graph  $G$  and that every two positive integers  $a$  and  $b$  with  $a \leq b \leq 2a + 1$  are realizable as the edge-to-edge detour radius and the edge-to-edge detour diameter, respectively, of some connected graph. Also it is shown that for any two positive integers  $a, b$  with  $a \leq b$  are realizable as the edge-to-edge radius and the edge-to-edge detour radius, respectively, of some connected graph and also for any two positive integers  $a, b$  with  $a \leq b$  are realizable as the edge-to-edge diameter and the edge-to-edge detour diameter, respectively, of some connected graph. Also we introduce the edge-to-edge detour center  $C_{D_3}(G)$  and the edge-to-edge detour periphery  $P_{D_3}(G)$ . It is shown that

---

the edge-to-edge detour center of every connected graph does not lie in a single block of  $G$ .

Key words : distance, detour distance, edge-to-edge detour distance.

AMS Subject Classification : 05C12.

## 1. Introduction

By a graph  $G = (V, E)$  we mean a finite undirected connected simple graph. For basic graph theoretic terminologies, we refer to Chartrand and Zhang [4]. If  $X \subseteq V$ , then  $X$  is the subgraph induced by  $X$ . For example if one is locating an emergency facility like police station, fire station, hospital, school, college, library, ambulance depot, emergency care center, etc., then the primary aim is to minimize the distance between the facility and the location of a possible emergency.

In 1964, Hakimi [6] considered the facility location problems as vertex-to-vertex distance in graphs. For any two vertices  $u$  and  $v$  in a connected graph  $G$ , the distance  $d(u, v)$  is the length of a shortest  $u - v$  path in  $G$ . For a vertex  $v$  in  $G$ , the eccentricity  $e(v)$  of  $v$  is the distance between  $v$  and a vertex farthest from  $v$  in  $G$ . The minimum eccentricity among the vertices of  $G$  is its radius and the maximum eccentricity is its diameter, denoted by  $\text{rad}(G)$  and  $\text{diam}(G)$  respectively. A vertex  $v$  in  $G$  is a central vertex if  $e(v) = \text{rad}(G)$  and the subgraph induced by the central vertices of  $G$  is the center  $\text{Cen}(G)$  of  $G$ . A vertex  $v$  in  $G$  is a peripheral vertex if  $e(v) = \text{diam}(G)$  and the subgraph induced by the peripheral vertices of  $G$  is the periphery  $\text{Per}(G)$  of  $G$ . If every vertex of  $G$  is a central vertex then  $G$  is called self-centered graph.

For example if one is making an election canvass or circular bus service the distance from the location is to be maximized. In 2005,

Chartrand et. al. [3] introduced and studied the concepts of detour distance in graphs. For any two vertices  $u$  and  $v$  in a connected graph  $G$ , the detour distance  $D(u, v)$  is the length of a longest  $u - v$  path in  $G$ . For a vertex  $v$  in  $G$ , the detour eccentricity  $e_D(v)$  of  $v$  is the detour distance between  $v$  and a vertex farthest from  $v$  in  $G$ . The minimum detour eccentricity among the vertices of  $G$  is its detour radius and the maximum detour eccentricity is its detour diameter, denoted by  $rad_D(G)$  and  $diam_D(G)$  respectively. The detour center, the detour self-centered and the detour periphery of a graph are defined similar to the center, the self-centered and the periphery of a graph, respectively.

For example when a railway line, pipe line or highway is constructed, the distance between the respective structure and each of the communities to be served is to be minimized. In a social network an edge represents two individuals having a common interest. Thus the centrality with respect to edges have interesting applications in social networks. In 2010, Santhakumaran [8] introduced the facility locational problem as edge-to-edge distance in graphs as follows: For any edges  $e$  and  $e'$  in a connected graph  $G$ , the edge-to-edge distance is defined by  $d(e, e') = \min\{d(u, v) : u \in e, v \in e'\}$ . The edge-to-edge eccentricity of  $e$  is defined by  $e_3(e) = \max\{d(e, e') : e' \in E\}$ . An edge  $f$  of  $G$  such that  $e_3(e) = d(e, f)$  is called an edge-to-edge eccentric edge of  $e$ . The edge-to-edge radius  $r_3$  of  $G$  is defined by  $r_3 = \min\{e_3(e) : e \in E\}$  and the edge-to-edge diameter  $d_3$  of  $G$  is defined by  $d_3 = \max\{e_3(e) : e \in E\}$ . An edge  $e$  for which  $e_3(e)$  is minimum is called an edge-to-edge central edge of  $G$  and the set of all edge-to-edge central edges of  $G$  is the edge-to-edge center  $C_3(G)$  of  $G$ . An edge  $e$  for which  $e_3(e)$  is maximum is called an edge-to-edge peripheral edge of  $G$  and the set

of all edge-to-edge peripheral edges of  $G$  is the edge-to-edge periphery  $P_3(G)$  of  $G$ . If every edge of  $G$  is an edge-to-edge central edge then  $G$  is called the edge-to-edge self-centered graph.

These motivated us to introduce a distance called the edge-to-edge detour distance in graphs and investigate certain results related to edge-to-edge detour distance and other distances in graphs. These ideas have interesting applications in channel assignment problem in radio technologies. Also there are useful applications of these concepts to security based communication network design. Throughout this paper,  $G$  denotes a connected graph with at least two vertices.

## 2. Edge-To-Edge Detour Distance

**Definition 2.1.** Let  $e$  and  $e'$  be any two edges in a connected graph  $G$ . An edge-to-edge  $e - e'$  path  $P$  is a  $u - v$  path, where  $u \in e$  and  $v \in e'$  such that  $P$  contains no vertices of  $e$  and  $e'$  other than  $u$  and  $v$  respectively. The edge-to-edge detour distance  $D(e, e')$  is the length of a longest  $e - e'$  path in  $G$ . An  $e - e'$  path of length  $D(e, e')$  is called an edge-to-edge  $e - e'$  detour or simply  $e - e'$  detour. For our convenience an  $e - e'$  path of length  $d(e, e')$  is called an edge-to-edge  $e - e'$  geodesic or simply  $e - e'$  geodesic.

**Example 2.2.** Consider the graph  $G$  given in Fig 2.1. For the edges  $e = \{u, w\}$  and  $e' = \{r, v\}$  in  $G$ , the paths  $P_1 : w, v$ ;  $P_2 : u, z, r$ ;  $P_3 : u, t, s, x, z, r$  and  $P_4 : u, t, s, x, y, z, r$  are  $e - e'$  paths, while the paths  $Q_1 : u, w, v$  and  $Q_2 : w, u, z, r, v$  are not  $e - e'$  paths. Now the edge-to-edge distance  $d(e, e') = 1$  and the edge-to-edge detour distance  $D(e, e') = 6$ .

Also  $P_1$  is an  $e - e'$  geodesic and  $P_4$  is an  $e - e'$  detour.

Fig 2.1: G

Since the length of an  $e - e'$  path between any two edges  $e$  and  $e'$  in a graph  $G$  of order  $n$  is at most  $n - 2$ , we have the following theorem.

Theorem 2.3. For any two edges  $e$  and  $e'$  in a non-trivial connected graph  $G$  of order  $n$ ,  $0 \leq d(e, e') \leq D(e, e') \leq n - 2$ .

Remark 2.4. The bounds in the Theorem 2.3 are sharp. For any two adjacent edges in a path of order  $n$ ,  $d(e, e') = D(e, e') = 0$  and for any two adjacent edges in a cycle of order  $n$ ,  $d(e, e') < D(e, e') = n - 2$ . If  $G$  is a tree of order  $n$  then,  $d(e, e') = D(e, e') < n - 2$ .

Theorem 2.5. Let  $K_{n,m}$  ( $n < m$ ) be a complete bipartite graph with the partition  $V_1, V_2$  of  $V(K_{n,m})$  such that  $|V_1| = n$  and  $|V_2| = m$ . Let  $e$  and  $e'$  be any two edges in  $K_{n,m}$ , then  $D(e, e') = 2n - 2$ .

Definition 2.6. The edge-to-edge detour eccentricity  $e_{D_3}(e)$  of an edge  $e$  in a connected graph  $G$  is defined as  $e_{D_3}(e) = \max \{D(e, e') : e' \in E\}$ . An edge  $f$  of  $G$  such that  $e_{D_3}(e) = D(e, f)$  is called an edge-to-edge detour

eccentric edge of  $e$ . The edge-to-edge detour radius of  $G$  is defined as,  $R_3 = \text{rad}_{D_3}(G) = \min \{e_{D_3}(e) : e \in E\}$  and the edge-to-edge detour diameter of  $G$  is defined as,  $D_3 = \text{diam}_{D_3}(G) = \max \{e_{D_3}(e) : e \in E\}$ . An edge  $e$  in  $G$  is called an edge-to-edge detour central edge if  $e_{D_3}(e) = R_3$  and the edge-to-edge detour center of  $G$  is defined as,  $C_{D_3}(G) = \text{Cen}_{D_3}(G) = \{e \in E : e_{D_3}(e) = R_3\}$ . An edge  $e$  in  $G$  is called an edge-to-edge detour peripheral edge if  $e_{D_3}(e) = D_3$  and the edge-to-edge detour periphery of  $G$  is defined as,  $P_{D_3}(G) = \text{Per}_{D_3}(G) = \{e \in E : e_{D_3}(e) = D_3\}$ . If every edge of  $G$  is an edge-to-edge detour central edge, then  $G$  is called an edge-to-edge detour self centered graph. If  $G$  is the edge-to-edge detour self centered graph then  $G$  is called the edge-to-edge detour periphery.

Example 2.7. For the connected graph  $G$  given in Fig. 2.2, the set of all edges in  $G$  are given by,  $E = \{e_1 = \{v_1, v_2\}, e_2 = \{v_1, v_3\}, e_3 = \{v_2, v_3\}, e_4 = \{v_3, v_4\}, e_5 = \{v_2, v_4\}, e_6 = \{v_4, v_5\}\}$ .

Fig. 2.2:  $G$

The edge-to-edge eccentricity  $e_3(e)$ , the edge-to-edge detour eccentricity  $e_{D_3}(e)$  of all the edges of  $G$  are given in Table 1.

$e$	$e_1$	$e_2$	$e_3$	$e_4$	$e_5$	$e_6$
$e_3(e)$	1	1	1	1	1	1
$e_{D_3}(e)$	2	2	1	2	2	2

Table 1

The edge-to-edge detour eccentric edge of all the edges of G are given in Table 2.

<i>Edge e</i>	<i>Edge-to-Edge Detour Eccentric Edge</i>
$e_2, e_3, e_5, e_6$	$e_1$
$e_1, e_3, e_4, e_6$	$e_2$
$e_3, e_5$	$e_4$
$e_3, e_4$	$e_5$
$e_1, e_2, e_3$	$e_6$

Table 2

The edge-to-edge radius  $r_3 = 1$ , the edge-to-edge diameter  $d_3 = 1$ , the edge-to-edge detour radius  $R_3 = 1$  and the edge-to-edge detour diameter  $D_3 = 2$ . Also the edge-to-edge center  $C_3(G) = \{e_1, e_2, e_3, e_4, e_5\}$ , the edge-to-edge periphery  $P_3(G) = \{e_1, e_2, e_3, e_4, e_5\}$ , the edge-to-edge detour center  $C_{D_3}(G) = \{e_3\}$  and the edge-to-edge detour periphery  $P_{D_3}(G) = \{e_1, e_2, e_4, e_5\}$ . It shows that edge-to-edge self-centered graph need not be edge-to-edge detour self-centered graph.

The edge-to-edge detour radius  $R_3$  and the edge-to-edge detour diameter  $D_3$  of some standard graphs are given in Table 3.

$G$	$K_n$	$P_n$	$C_n(n \geq 4)$	$W_n(n \geq 4)$	$K_{n,m}(m \geq n)$
$R_3$	$n - 2$	$\lfloor \frac{n-3}{2} \rfloor$	$n - 2$	$n - 2$	$2n - 2$
$D_3$	$n - 2$	$n - 3$	$n - 2$	$n - 2$	$2n - 2$

Table 3

Example 2.8. The complete graph  $K_n$ , the cycle  $C_n$ , the wheel  $W_n$  and the complete bipartite graph  $K_{n,m}$  are the edge-to-edge detour self centered graphs.

The following theorem is a consequence of Theorem 2.3.

Theorem 2.9. Let  $G$  be a connected graph. Then

- (i)  $0 \leq e_3(e) \leq e_{D_3}(e) \leq n - 2$  for every edge  $e$  in  $G$ .
- (i)  $0 \leq r_3 \leq R_3 \leq n - 2$ .
- (ii)  $0 \leq d_3 \leq D_3 \leq n - 2$ .

Remark 2.10. The bounds in the Theorem 2.9 (i) are sharp. If  $G = P_3$ , then  $e_3(e) = e_{D_3}(e) = 0$  for every edge  $e$  in  $G$  and if  $G=C_n$ , then  $e_3(e) = e_{D_3}(e) = n - 2$  for every edge  $e$  in  $G$ . Also we note that if  $G$  is a tree, then  $e_3(e) = e_{D_3}(e)$  for every edge  $e$  in  $G$  and for the graph  $G$  given in Fig. 2.1,  $0 < e_3(e) < e_{D_3}(e) < n - 2$ , where  $e = \{u, z\}$ .

Theorem 2.11. For every connected graph  $G$ ,  $R_3 \leq D_3 \leq 2R_3+1$ .

*Proof.* By definition  $R_3 \leq D_3$ . Now let  $P : u_1, u_2, \dots, u_{n-1}, u_n$  be an edge-to-edge diametral path of length  $D_3$  connecting an edge  $e$  and  $e'$ , where  $e = \{u_1, u_2\}$  and  $e' = \{u_{n-1}, u_n\}$ , so that  $D_3 = D(e, e') = D(u_2, u_{n-1})$  and let  $f$  be a edge of  $G$  such that  $e_{D_3}(f) = R_3 = D(y, u_{n-1}) = D(x, u_2)$ , where  $f = \{x, y\}$ . It follows that  $D_3 = D(e, e') \leq D(e, f) + D(x, y) + D(f, e') \leq R_3 + 1 + R_3 \leq 2R_3 + 1$ .

Remark 2.12. *The bounds in the Theorem 2.11 are sharp. For the graph  $G$  given in Fig 2.3, it is easy to verify that  $R_3 = 2$  and  $D_3 = 5$ .*

Fig. 2.3: G

Ostrand [7] showed that every two positive integers  $a$  and  $b$  with  $a \leq b \leq 2a$  are realizable as the radius and diameter respectively of some connected graph and Chartrand et. al. [3] showed that every two positive integers  $a$  and  $b$  with  $a \leq b \leq 2a$  are realizable as the detour radius and detour diameter respectively of some connected graph. Now we have a realization theorem for the edge-to-edge detour radius and the edge-to-edge detour diameter of some connected graph.

**Theorem 2.13.** For each pair  $a, b$  of positive integers with  $a \leq b \leq 2a+1$ , there exists a connected graph  $G$  with  $R_3 = a$  and  $D_3 = b$ .

**Proof.** Case 1.  $a = b$ . Let  $G = C_{a+3}$ :  $u_1, u_2, \dots, u_{a+3}, u_1$  be a cycle of order  $a + 3$ . Then  $e_{D_3}(u_i, u_{i+1}) = a$  for  $1 \leq i \leq a + 2$ . Thus  $R_3 = a$  and  $D_3 = b$  as  $a = b$ .

Case 2.  $b \leq 2a$ . Let  $C_{a+3}$ :  $u_1, u_2, \dots, u_{a+3}, u_1$  be a cycle of order  $a + 3$

and  $P_{b-a+1} : v_1, v_2, \dots, v_{b-a+1}$  be a path of order  $b - a + 1$ . We construct the graph  $G$  of order  $b + 3$  by identifying the vertex  $u_1$  of  $C_{a+3}$  and  $v_1$  of  $P_{b-a+1}$  as shown in Fig. 2.4. It is easy to verify that  $e_{D_3}(u_1 u_2) = e_{D_3}(u_1 u_{a+3}) = a$ . Also  $e_{D_3}(u_i u_{i+1}) = b-i+2$  for  $2 \leq i \leq \lfloor (a+3)/2 \rfloor$  and  $e_{D_3}(u_i u_{i+1}) = b-a+i-2$  for  $\lfloor (a+3)/2 \rfloor < i \leq a+2$ . Also  $e_{D_3}(v_i v_{i+1}) = a+i$  for  $1 \leq i \leq b - a$ . In particular,  $e_{D_3}(u_2 u_3) = e_{D_3}(u_{a+2} u_{a+3}) = e_{D_3}(v_{b-a} v_{b-a+1}) = b$ . It is easy to verify that there is no edge  $e$  in  $G$  with  $e_{D_2}(e) < a$  and there is no edge  $e'$  in  $G$  with  $e_{D_2}(e') > b$ . Thus  $R_2 = a$  and  $D_2 = b$  as  $a < b \leq 2a$ .

Fig. 2.4:  $G$

Case 3.  $b = 2a + 1$ . Construct the graph  $G$  as shown in Fig 2.5, it is easy to verify that  $e_{D_3}(xv_1) = a$  and  $e_{D_3}(v_{b-a}v_{b-a+1}) = b$ . Also there is no edge  $e$  in  $G$  with  $e_{D_3}(e) < a$  and there is no edge  $e'$  in  $G$  with  $e_{D_3}(e') > b$ . Thus  $R_3=a$  and  $D_3 = b$  as  $b = 2a+1$ .

Fig. 2.5: G

Chartrand et. al. [3] showed that every pair  $a, b$  of positive integers with  $a \leq b$  is realizable as the radius and the detour radius of some connected graph. Now we have a realization theorem for the edge-to-edge radius and the edge-to-edge detour radius of some connected graph.

**Theorem 2.14.** For each pair  $a, b$  of positive integers with  $a \leq b$ , there exists a connected graph  $G$  such that  $r_3 = a$  and  $R_3 = b$ .

*Proof.* Case 1.  $a = b$ . Let  $P_1 : u_1, u_2, \dots, u_a, u_{a+2}$  and  $P_2 : v_1, v_2, \dots, v_a, v_{a+2}$  be two paths of order  $a+2$ . We construct the graph  $G$  of order  $2a + 4$  by joining  $u_1$  in  $P_1$  and  $v_1$  in  $P_2$  by an edge. Then  $e_3(u_1 v_1) = e_{D_3}(u_1 v_1) = a$  and  $e_3(u_i u_{i+1}) = e_3(v_i v_{i+1}) = a + i$  for  $1 \leq i \leq a+1$ . It is easy to verify that there is no edge  $e$  in  $G$  with  $e_3(e) = e_{D_3}(e) < a$ . Thus  $r_3 = a$  and  $R_3 = b$  as  $a = b$ .

Case 2.  $a < b$ . We have the following two subcases:

Subcase 1 of Case 2.  $a = 1$ . Any complete graph of order  $K_{b+2}$  is the desired graph.

Subcase 2 of Case 2.  $a \geq 2$ . Let  $P_1 : u_1, u_2, \dots, u_a, u_{a+2}$  and  $Q_1 : v_1, v_2, \dots, v_a, v_{a+2}$  be two paths of order  $a + 2$ . Let  $P_2 : w_1, w_2, \dots, w_{b-a+2}$  and  $Q_2 : z_1, z_2, \dots, z_{b-a+2}$  be two paths of order  $b - a + 2$ . We construct the graph  $G$  of order  $2b + 2$  as follows: (i) identify the vertices  $u_1$  in  $P_1$  with  $w_1$  in  $P_2$  and also identify the vertices  $v_1$  in  $Q_1$  with  $z_1$  in  $Q_2$  (ii) identify the vertices  $u_3$  in  $P_1$  with  $w_{b-a+2}$  in  $P_2$  and also identify the vertices  $z_{b-a+2}$  in  $Q_2$  with  $v_3$  in  $Q_1$  (iii) join each vertex  $w_i$  ( $2 \leq i \leq b - a + 1$ ) in  $P_2$  with  $u_2$  in  $P_1$  and join each vertex  $z_i$  ( $2 \leq i \leq b - a + 1$ ) in  $Q_2$  with  $v_2$  in  $Q_1$  (iv) join  $u_1$  in  $P_1$  with  $v_1$  in  $Q_1$ . The resulting graph  $G$  is shown in Fig. 2.6.

Fig. 2.6: G

It is easy to verify that

$$e_3(u_1v_1) = a$$

$$e_3(u_iu_{i+1}) = a + i \text{ if } 1 \leq i \leq a + 1$$

$$e_3(v_iv_{i+1}) = a + i \text{ if } 1 \leq i \leq a + 1$$

$$e_3(w_iw_{i+1}) = \begin{cases} a + 1, & \text{if } i = 1 \\ a + 2, & \text{if } i = 2 \\ a + 3, & \text{if } 3 \leq i \leq b - a + 1 \end{cases}$$

$$\begin{aligned}
e_3(z_i z_{i+1}) &= \begin{cases} a+1, & \text{if } i=1 \\ a+2, & \text{if } i=2 \\ a+3, & \text{if } 3 \leq i \leq b-a+1 \end{cases} \\
e_3(u_2 w_i) &= a+2 \quad \text{if } 1 \leq i \leq b-a+1 \\
e_3(v_2 z_i) &= a+2 \quad \text{if } 1 \leq i \leq b-a+1 \\
e_{D_3}(u_1 v_1) &= b \\
e_{D_3}(u_i u_{i+1}) &= \begin{cases} b+1, & \text{if } i=1 \\ 2b-a+i, & \text{if } 2 \leq i \leq a+1 \end{cases} \\
e_{D_3}(v_i v_{i+1}) &= \begin{cases} b+1, & \text{if } i=1 \\ 2b-a+i, & \text{if } 2 \leq i \leq a+1 \end{cases} \\
e_{D_3}(w_i w_{i+1}) &= \begin{cases} b+1, & \text{if } i=1 \\ 2b-a+2, & \text{if } 2 \leq i \leq b-a+1 \end{cases} \\
e_{D_3}(z_i z_{i+1}) &= \begin{cases} b+1, & \text{if } i=1 \\ 2b-a+2, & \text{if } 2 \leq i \leq b-a+1 \end{cases} \\
e_{D_3}(u_2 w_i) &= b+i \quad \text{if } 1 \leq i \leq b-a+1 \\
e_{D_3}(v_2 z_i) &= b+i \quad \text{if } 1 \leq i \leq b-a+1
\end{aligned}$$

It is easy to verify that there is no edge  $e$  in  $G$  with  $e_3(e) < a$  and  $e_{D_3}(e) < b$ . Thus  $r_3 = a$  and  $R_3 = b$  as  $a < b$ .

Chartrand et. al. [3] showed that every pair  $a, b$  of positive integers with  $a \leq b$  is realizable as the diameter and the detour diameter of some connected graph. Now we have a realization theorem for the edge-to-edge diameter and the edge-to-edge detour diameter of some connected graph.

**Theorem 2.15.** For any two positive integers  $a, b$  with  $a \leq b$ , there exists a connected graph  $G$  such that  $d_3 = a$  and  $D_3 = b$ .

**Proof.** Case 1.  $a = b$ . Let  $P_{a+2}: u_1, u_2, \dots, u_{a+2}, u_{a+3}$  be a path of order  $a+3$ . Then  $e_3(u_i u_{i+1}) = e_{D_3}(u_i u_{i+1}) = a - i + 2$  for  $1 \leq i \leq \lceil (a+2)/2 \rceil$  and

$e_3(u_i u_{i+1}) = e_{D_3}(u_i u_{i+1}) = i - 2$  for  $\lceil (a+2)/2 \rceil < i \leq a + 1$ . In particular  $e_3(u_1 u_2) = e_{D_3}(u_1 u_2) = e_3(u_{a+2} u_{a+3}) = e_{D_3}(u_{a+2} u_{a+3}) = a$ . It is easy to verify that there is no edge  $e$  in  $G$  with  $e_3(e) = e_{D_3}(e) > a$ . Thus  $d_3 = a$  and  $D_3 = b$  as  $a = b$ .

Case 2.  $a < b$ . We have the following two subcases:

Subcase 1 of Case 2.  $a = 1$ . Any complete graph of order  $K_{b+2}$  is the desired graph.

Subcase 2 of Case 2.  $a = 2$ . Let  $G$  be the graph obtained by joining any one vertex of the complete graph  $K_b$  of order  $b$  with any vertex of a path  $P_3 : x_1, x_2, x_3, x_4$  of order 4. It is easy to verify that  $e_3(x_3 x_4) = a$  and  $e_{D_3}(x_3 x_4) = b$ . Also there is no edge  $e$  in  $G$  with  $e_3(e) > a$  and  $e_{D_3}(e) > b$ .

Subcase 3 of Case 2.  $a \geq 3$ . Let  $P_1 : u_1, u_2, \dots, u_{a+1}, u_{a+2}$  be a path of order  $a + 1$ . Let  $P_2 : w_1, w_2, \dots, w_{b-a+2}$  be a path of order  $b - a + 2$ . Let  $P_3 : x_1, x_2$  be a path of order 2. We construct the graph  $G$  of order  $b + 3$  as follows: (i) identify the vertices  $u_1$  in  $P_1$ ,  $w_1$  in  $P_2$  with  $x_1$  in  $P_3$  and identify the vertices  $u_3$  in  $P_1$  with  $w_{b-a+2}$  in  $P_2$  (ii) join each vertex  $w_i$  ( $2 \leq i \leq b - a + 1$ ) in  $P_2$  with  $u_2$  in  $P_1$ . The resulting graph  $G$  is shown in Fig. 2.7.

Fig 2.7

It is easy to verify that

$$e_3(x_1x_2) = a$$

$$e_{D_3}(x_1x_2) = b$$

$$e_3(u_iu_{i+1}) = \begin{cases} a - i, & \text{if } 1 \leq i \leq \lfloor \frac{a}{2} \rfloor \\ i - 1, & \text{if } \lfloor \frac{a}{2} \rfloor < i \leq a + 1 \end{cases}$$

$$e_{D_3}(u_iu_{i+1}) = \begin{cases} b - 1, & \text{if } i = 1 \\ b - a + i - 1, & \text{if } 2 \leq i \leq a \text{ for } b - a + i - 1 \geq a - i \\ a - i, & \text{if } 2 \leq i \leq a \text{ for } b - a + i - 1 \leq a - i \end{cases}$$

$$e_3(u_2w_i) = a - 1 \text{ if } 2 \leq i \leq b - a + 1$$

$$\begin{aligned}
e_{D_3}(u_2w_i) &= \begin{cases} b-i, & \text{if } 1 \leq i \leq b-a+1 \text{ for } b-i \geq i \\ i-1, & \text{if } 1 \leq i \leq b-a+1 \text{ for } b-i \leq i \end{cases} \\
e_3(w_iw_{i+1}) &= \begin{cases} a, & \text{if } 1 \leq i \leq b-a-1 \\ a-1, & \text{if } i = b-a \\ a-2, & \text{if } i = b-a+1 \text{ for } a-2 \geq a \\ a-1, & \text{if } i = b-a+1 \text{ for } a-2 \leq a-1 \end{cases} \\
e_{D_3}(w_iw_{i+1}) &= \begin{cases} b-1, & \text{if } 1 \leq i \leq b-a \\ b-a+1, & \text{if } i = b-a+1 \text{ for } b-a+2 \geq a-2 \\ a-2, & \text{if } i = b-a+1 \text{ for } b-a+2 \leq a-2 \end{cases}
\end{aligned}$$

It is easy to verify that there is no edge  $e$  in  $G$  with  $e_3(e) > a$  and  $e_{D_3}(e) > b$ . Thus  $d_3 = a$  and  $D_3 = b$  as  $a < b$ .

Problem 2.16. Characterize the graphs such that  $C_{D_3}(G) = C_3(G)$

Problem 2.17. Characterize the graphs such that  $P_{D_3}(G) = P_3(G)$

Problem 2.18. Characterize the graphs such that  $C_{D_3}(G) = P_{D_3}(G)$

Problem 2.19. Is every graph an edge-to-edge detour center of some graph?

Remark 2.20. The edge-to-edge detour center of every connected graph does not lie in a single block of  $G$ . For the Path  $P_{2n+1}$  of order  $2n+1$ , the edge-to-edge detour center is always  $P_3$ , which does not lie in a single block.
